# Edge Detection

CS 543 / ECE 549 – Saurabh Gupta  
Spring 2021, UIUC

<http://saurabhg.web.illinois.edu/teaching/ece549/sp2021/>

# Edge detection

---

- **Goal:** Identify sudden changes (discontinuities) in an image
- Intuitively, edges carry most of the semantic and shape information from the image

# Edge detection

---

**Ideal:** artist's line drawing

**Reality**

# Edge detection

---

- An edge is a place of rapid change in the image intensity function

# Derivatives with convolution

For 2D function  $f(x,y)$ , the partial derivative is:

$$\frac{\partial f(x, y)}{\partial x} = \lim_{\varepsilon \rightarrow 0} \frac{f(x + \varepsilon, y) - f(x, y)}{\varepsilon}$$

For discrete data, we can approximate using finite differences:

$$\frac{\partial f(x, y)}{\partial x} \approx \frac{f(x + 1, y) - f(x, y)}{1}$$

To implement the above as convolution, what would be the associated filter?

# Partial derivatives of an image

$$\frac{\partial f(x, y)}{\partial x}$$

$$\frac{\partial f(x, y)}{\partial y}$$

-1	1
----	---

-1	or	1
1		-1

Which shows changes with respect to x?

# Finite difference filters

---

Other approximations of derivative filters exist:

- Prewitt

$$M_x \begin{array}{|c|c|c|} \hline -1 & 0 & 1 \\ \hline -1 & 0 & 1 \\ \hline -1 & 0 & 1 \\ \hline \end{array}$$

$$M_y \begin{array}{|c|c|c|} \hline 1 & 1 & 1 \\ \hline 0 & 0 & 0 \\ \hline -1 & -1 & -1 \\ \hline \end{array}$$

- Sobel

$$M_x \begin{array}{|c|c|c|} \hline -1 & 0 & 1 \\ \hline -2 & 0 & 2 \\ \hline -1 & 0 & 1 \\ \hline \end{array}$$

$$M_y \begin{array}{|c|c|c|} \hline 1 & 2 & 1 \\ \hline 0 & 0 & 0 \\ \hline -1 & -2 & -1 \\ \hline \end{array}$$

- Roberts

$$M_x \begin{array}{|c|c|} \hline 0 & 1 \\ \hline -1 & 0 \\ \hline \end{array}$$

$$M_y \begin{array}{|c|c|} \hline 1 & 0 \\ \hline 0 & -1 \\ \hline \end{array}$$

# Image gradient

---

The gradient of an image:  $\nabla f = \left[ \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right]$

The gradient points in the direction of most rapid increase in intensity

- How does this direction relate to the direction of the edge?

The gradient direction is given by  $\theta = \tan^{-1} \left( \frac{\partial f}{\partial y} / \frac{\partial f}{\partial x} \right)$

The edge strength is given by the gradient magnitude

$$\|\nabla f\| = \sqrt{\left(\frac{\partial f}{\partial x}\right)^2 + \left(\frac{\partial f}{\partial y}\right)^2}$$

# Application: Gradient-domain image editing

- Goal: solve for pixel values in the target region to match gradients of the source region while keeping background pixels the same

sources/destinations

cloning

seamless cloning

P. Perez, M. Gangnet, A. Blake, [Poisson Image Editing](#), SIGGRAPH 2003

# Effects of noise

---

Consider a single row or column of the image

Where is the edge?

# Solution: smooth first

- To find edges, look for peaks in  $\frac{d}{dx}(f * g)$

# Derivative theorem of convolution

- Differentiation is convolution, and convolution is associative:  $\frac{d}{dx}(f * g) = f * \frac{d}{dx}g$
- This saves us one operation:

# Derivative of Gaussian filters

---

x-direction

y-direction

Which one finds horizontal/vertical edges?

# Derivative of Gaussian filters

---

x-direction

y-direction

Are these filters separable?

# Recall: Separability of the Gaussian filter

---

$$\begin{aligned} G_{\sigma}(x, y) &= \frac{1}{2\pi\sigma^2} e^{-\left(\frac{x^2+y^2}{2\sigma^2}\right)} \\ &= \left( \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{x^2}{2\sigma^2}} \right) \left( \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{y^2}{2\sigma^2}} \right) \end{aligned}$$

The 2D Gaussian can be expressed as the product of two functions, one a function of  $x$  and the other a function of  $y$ .

In this case the two functions are the (identical) 1D Gaussian.

# Scale of Gaussian derivative filter

---

1 pixel

3 pixels

7 pixels

Smoothed derivative removes noise, but blurs edge. Also finds edges at different “scales”

# Review: Smoothing vs. derivative filters

## Smoothing filters

- Gaussian: remove “high-frequency” components; “low-pass” filter
- Can the values of a smoothing filter be negative?
- What should the values sum to?
  - **One**: constant regions are not affected by the filter

## Derivative filters

- Derivatives of Gaussian
- Can the values of a derivative filter be negative?
- What should the values sum to?
  - **Zero**: no response in constant regions

# Building an edge detector

original image

final output

# Building an edge detector

---

norm of the gradient

# Building an edge detector

---

$$\theta = \text{np.arctan2}(-g_y, g_x)$$

orientation of the gradient

# Building an edge detector

---

How to turn these thick regions of the gradient into curves?

Norm of the gradient  $>$  threshold

# Non-maximum suppression

---

- For each location  $q$  above threshold, check that the gradient magnitude is higher than at neighbors  $p$  and  $r$  along the direction of the gradient
  - May need to interpolate to get the magnitudes at  $p$  and  $r$

# Bilinear Interpolation

$$f(x, y) \approx \begin{bmatrix} 1 - x & x \end{bmatrix} \begin{bmatrix} f(0,0) & f(0,1) \\ f(1,0) & f(1,1) \end{bmatrix} \begin{bmatrix} 1 - y \\ y \end{bmatrix}$$

# Sidebar: Interpolation options

---

```
imx2 = imresize(im, 2,  
interpolation_type)
```

## ‘nearest’

- Copy value from nearest known
- Very fast but creates blocky edges

## ‘bilinear’

- Weighted average from four nearest known pixels
- Fast and reasonable results

## ‘bicubic’ (default)

- Non-linear smoothing over larger area
- Slower, visually appealing, may create negative pixel values

# Non-maximum suppression

---

NMS

NMS > threshold

Another problem: pixels along this edge didn't survive the thresholding

# Hysteresis thresholding

---

Use a high threshold to start edge curves, and a low threshold to continue them.

# Hysteresis

---

**high threshold  
(strong edges)**

**low threshold  
(weak edges)**

**hysteresis threshold**

# Hysteresis thresholding

---

**original image**

**high threshold  
(strong edges)**

**low threshold  
(weak edges)**

**hysteresis threshold**

# Effect of $\sigma$ (Gaussian kernel spread/size)

---

original

Canny with  $\sigma = 1$

Canny with  $\sigma = 2$

The choice of  $\sigma$  depends on desired behavior

- large  $\sigma$  detects large scale edges
- small  $\sigma$  detects fine features

# Recap: Canny edge detector

---

1. Compute x and y gradient images
2. Find magnitude and orientation of gradient
3. **Non-maximum suppression:**
  - Thin wide “ridges” down to single pixel width
4. **Linking and thresholding (hysteresis):**
  - Define two thresholds: low and high
  - Use the high threshold to start edge curves and the low threshold to continue them

# Do humans consistently segment images?

Divide each image into pieces, where each piece represents a distinguished thing in the image. It is important that all of the pieces have approximately equal importance. The number of things in each image is up to you. Something between 2 and 20 should be reasonable for any of our images.

# State of edge detection

---

Local edge detection is mostly solved

- Intensity gradient, color, texture
- HED on BSDS 500 is near human performance

Some room for improvement by taking advantage of higher-level knowledge (e.g., objects)

Still hard to produce all objects within a small number of regions
