## Color

## CS 543 / ECE 549 - Saurabh Gupta

## While we wait, what color is the dress?

- A. White and gold
- B. Blue and Black
https://www.wired.com/2015/02/science-one-agrees-color-dress/

## What is color?

- Color is the result of interaction between physical light in the environment and our visual system
- Color is a psychological property of our visual experiences when we look at objects and lights, not a physical property of those objects or lights (S. Palmer, Vision Science: Photons to Phenomenology)

## Outline

- Physical origin of color
- Spectra of sources and surfaces
- Physiology of color vision
- Trichromatic color theory
- Color spaces
- Color constancy, white balance

## Electromagnetic spectrum

Human Luminance Sensitivity Function

## The Physics of Light

Any source of light can be completely described physically by its spectrum: the amount of energy emitted (per time unit) at each wavelength $400-700 \mathrm{~nm}$.

## Spectra of Light Sources

## Some examples of the spectra of light sources

A. Ruby Laser

C. Tungsten Lightbulb

B. Gallium Phosphide Crystal

D. Normal Daylight

## Spectra of light sources

WAVELENGTH (nanometers)
Source: Popular Mechanics

## Reflectance Spectra of Surfaces

## Some examples of the reflectance spectra of surfaces

## Interaction of light and surfaces

- Reflected color is the result of interaction of light source spectrum with surface reflectance

## So, what is the dimensionality of color?

- A. 3
- B. $(255)^{\wedge} 3$
- C. 255
- D. Infinite

## The Eye

## The human eye is a camera!

- Lens - changes shape by using ciliary muscles (to focus on objects at different distances)
- Pupil - the hole (aperture) whose size is controlled by the iris
- Iris - colored annulus with radial muscles
- Retina - photoreceptor cells

## Rods and cones, fovea

Rods are responsible for intensity, cones for color perception
Rods and cones are non-uniformly distributed on the retina

- Fovea - Small region (1 or $2^{\circ}$ ) at the center of the visual field containing the highest density of cones - and no rods

## Rod / Cone sensitivity

Why can't we read in the dark?

## Physiology of Color Vision

## Three kinds of cones:

WAVELENGTH (nm.)

- Ratio of L to M to S cones: approx. 10:5:1
- Almost no S cones in the center of the fovea

## Physiology of Color Vision: Fun facts

- " M " and " L " pigments are encoded on the X-chromosome
- That's why men are more likely to be color blind
- "L" gene has high variation, so some women may be tetrachromatic
- Some animals have one (night animals), two (e.g., dogs), four (fish, birds), five (pigeons, some reptiles/amphibians), or even 12 (mantis shrimp) types of cones http://ngm.nationalgeographic.com/2016/02/evolution-of-eyes-text

## Color perception

Wavelength

## Rods and cones act as filters on the spectrum

- To get the output of a filter, multiply its response curve by the spectrum, integrate over all wavelengths
- Each cone yields one number
- How can we represent an entire spectrum with three numbers?
- We can't! Most of the information is lost
- As a result, two different spectra may appear indistinguishable » such spectra are known as metamers

## Color matching experiments

- We would like to understand which spectra produce the same color sensation in people under similar viewing conditions

## Color matching experiment 1

## Color matching experiment 1

## Color matching experiment 1

## Color matching experiment 1

The primary color amounts needed for a match

## Color matching experiment 2

## Color matching experiment 2

## Color matching experiment 2

## Color matching experiment 2

We say a "negative" amount of $p_{2}$ was needed to make the match, because we added it to the test color's side.

The primary color amounts needed for a match:

Source: W. Freeman

## Trichromacy

- In color matching experiments, most people can match any given light with three primaries
- Primaries must be independent
- For the same light and same primaries, most people select the same weights
- Exception: color blindness
- Trichromatic color theory
- Three numbers seem to be sufficient for encoding color
- Dates back to $18^{\text {th }}$ century (Thomas Young)

## Artificial Cones

Resulting Pattern

## Color Image

Slide Credit: J. Hays

## Color Image

Slide Credit: J. Hays

## One Option: RGB

Pros<br>1. Simple<br>2. Common

## Cons

1. Distances don't make sense 2. Correlated

## RGB

## Another Option: HSV

## Pros

1. Intuitive for picking colors
2. Sort of common
3. Fast to convert

Cons

1. Not as perceptual

S
$(\mathrm{H}=1, \mathrm{~V}=1)$

V
$(\mathrm{H}=1, \mathrm{~S}=0)$

Slide Credit: J. Hays, HSV cylinder: https://en.wikipedia.org/wiki/HSL_and_HSV

## HSV

## Another Option: Lab

## Pros <br> 1. Distances correspond with human judgment

## Cons

1. Complex to calculate

## a

(L=65,b=0)
b
(L=65,a=0)

## Lab

Photo credit: J. Hays

## Why Are There So Many?

- Each serves different functions
- RGB: sort of intuitive, standard, everywhere
- HSV: good for picking, fast to compute
- YCbCr/YUV: fast to compute, compresses well
- Lab: the right(?) thing to do, but "slow" to compute
- Pick based on what you need and don't sweat it: color really isn't crucial

## Color perception

- Color/lightness constancy
- The ability of the human visual system to perceive the intrinsic reflectance properties of the surfaces despite changes in illumination conditions

## Checker shadow illusion

## Checker shadow illusion

- Possible explanations
- Simultaneous contrast
- Reflectance edges vs. illumination edges

## What color is the dress?

https://www.wired.com/2015/02/science-one-agrees-color-dress/

## This strawberry cake has no red pixels!

https://www.digitaltrends.com/photography/non-red-strawberries/

## White balance

- Analogous to color constancy mechanisms in human vision, cameras have mechanisms to adapt to the illumination in the environment so that neutral (white or gray) objects look neutral

Correct white balance

## White balance

- Film cameras:
- Different types of film or different filters for different illumination conditions
- Digital cameras:
- Automatic white balance
- White balance settings corresponding to several common illuminants
- Custom white balance using a reference object

## White balance

- Von Kries adaptation: Multiply each channel by a gain factor
- Best way: gray card
- Take a picture of a neutral object (white or gray)
- If the object is recorded as $r_{w}, g_{w}, b_{w}$ use weights $1 / r_{w}, 1 / g_{w}, 1 / b_{w}$

## White balance

- Without gray cards: we need to "guess" which pixels correspond to white objects
- Gray world assumption
- The image average $\mathrm{r}_{\text {ave }}, \mathrm{g}_{\text {ave }}, \mathrm{b}_{\text {ave }}$ is gray
- Use weights $1 / r_{\mathrm{ave}}, 1 / \mathrm{g}_{\mathrm{ave}}, 1 / \mathrm{b}_{\mathrm{ave}}$
- Brightest pixel assumption
- Highlights usually have the color of the light source
- Use weights inversely proportional to the values of the brightest pixels
- Gamut mapping
- Gamut: convex hull of all pixel colors in an image
- Find the transformation that matches the gamut of the image to the gamut of a "typical" image under white light
- Use image statistics, learning techniques

## Mixed illumination

- When there are several types of illuminants in the scene, different reference points will yield different results

Reference: moon

Reference: stone
